2.3 Distribution of missing values by year 8

Abstract

This paper presents a rigorous comparative analysis of the beef sector in Ireland, encompassing a wide range of key dimensions, including production, consumption, and trade. By leveraging both historical and contemporary data, the paper employs various forecasting models to project future beef prices in the Irish market. Additionally, the study integrates sentiment analysis to extract valuable insights into public perception of the beef industry. Through a combination of quantitative and qualitative analysis, the paper provides a comprehensive understanding of the industry, outlining key trends and offering strategic recommendations for relevant stakeholders. The research was carried out by Ronan Downes, with the goal of contributing to ongoing discussions around the optimisation of Ireland's beef sector.

Chapter 1

Introduction

1.1 Background and objectives of the study

1.1.1 Global Beef Industry

The global beef industry is a significant contributor to the world economy, with an estimated value of around $300 billion. The industry is dominated by countries such as the United States, Brazil, Argentina, and Australia, which are the largest producers and exporters of beef. China and the European Union are also major players in the global beef market.

The demand for beef is increasing globally, driven by population growth, increasing per capita income, and changing dietary patterns. However, the industry faces challenges such as environmental concerns, animal welfare issues, and health concerns, which have led to increased demand for plant-based alternatives (Trostle 2010).

1.1.2 Irish Beef Industry

The Irish beef industry is an important part of the country's economy and heritage, with a long history of cattle farming. Ireland is one of the largest beef exporters in the European Union, and the industry is a significant employer in rural areas.

The Irish beef industry prides itself on its grass-fed cattle, which is seen as a key selling point for the high quality and taste of Irish beef. The industry is regulated by the Department of Agriculture, Food and the Marine, which has implemented measures to ensure high standards of animal welfare, food safety, and environmental sustainability.

However, the industry faces challenges such as Brexit, which has disrupted trade with the United Kingdom, one of its main markets, and increasing competition from other beef-producing countries. The industry is also under pressure to address concerns about its environmental impact, particularly in relation to greenhouse gas emissions from cattle farming.

1.1.3 The European Union's (EU) Common Agricultural Policy (CAP)

The European Union's (EU) Common Agricultural Policy (CAP) provides various incentives for beef production. These incentives are designed to support and promote sustainable and competitive beef production in the EU, while also ensuring high quality standards and animal welfare.

One key incentive is the direct payments provided to farmers through the CAP's Basic Payment Scheme (BPS). This scheme provides financial support to farmers who meet certain requirements related to the environment, food safety, and animal welfare. In addition, the CAP also offers coupled support for beef farmers, which provides additional financial support to farmers who are producing beef cattle in regions where there is limited potential for other agricultural activities.

The CAP also includes measures to promote sustainable beef production, such as funding for agri-environmental measures that encourage the use of sustainable farming practices, such as reducing greenhouse gas emissions, improving soil quality, and protecting biodiversity.

Furthermore, the EU has implemented programs such as the Beef and Veal Promotion Program, which aims to promote beef consumption and increase consumer awareness about the benefits of beef produced in the EU. This program provides funding for promotional activities and campaigns that highlight the quality, taste, and nutritional value of EU-produced beef.

Overall, the EU CAP provides various incentives and programs to support and promote sustainable and competitive beef production in the EU, while also ensuring high standards for animal welfare and environmental sustainability.

1.2 Significance of the beef sector in Ireland

1.2.1 Economic importance

The beef sector in Ireland is a crucial contributor to the country's GDP, employment, and exports. According to the Irish Department of Agriculture, Food, and the Marine, the beef sector is one of the most important sectors of the Irish economy. It accounts for approximately €2.5 billion in output and supports over 100,000 jobs (*gov.ie - Department of Agriculture, Food and the Marine* n.d.).

The beef sector is an important contributor to the Irish economy as it provides direct and indirect employment opportunities. The direct employment created by the sector includes farmers, veterinarians, and meat processors, while indirect employment is created through the supply chain, which includes feed suppliers, equipment manufacturers, and transportation services (ibid.).

Furthermore, the sector plays a crucial role in the country's export market, generating significant revenue for the Irish economy. The European Union is the largest market for Irish beef, accounting for more than 50% of its total exports. The United Kingdom is the largest individual market for Irish beef, accounting for around 35% of total exports. Other countries to which Irish beef is exported include the United States, China, and Japan (*Meat Industry - Bord Bia | Irish Food Board* n.d.).

In addition to its direct economic contributions, the beef sector also has important social and cultural significance in Ireland. Beef farming is a traditional occupation and an important part of rural life in many parts of the country. The sector also plays a role in maintaining the country's cultural heritage and identity (Loughrey et al. 2018).

In conclusion, the beef sector is a critical contributor to the Irish economy, providing significant economic benefits through its contribution to GDP, employment, and exports. Its importance extends beyond the economic realm, however, as it also plays a vital role in the country's cultural heritage and identity.

Chapter 2

Methodology

2.1 Data collection and sources

2.2 Structure of the data

Taking a higher-level view of the data before performing detailed exploratory data analysis (EDA) it helps to understanding the dataset's size and shape, as well as any high-level patterns or trends that may be present. The output of df.shape tells us that the dataset contains 1708 rows and 14 columns which is a small number of data points of low dimensionality. The scope of the analysis need not be reconsidered (Páez and Boisjoly 2023).

2.3 The df.nunique() method

The df.nunique() method was used to generate table . Seven of the Columns have unique value and do not provide useful information for exploratory data analysis (EDA). These columns refereed to as constant due to their absents of variation and can have no predictive value in our machine learning model.

Nevertheless, data cleaning best practice is to exercise caution before dropping columns in case they are constant due to errors or inconsistencies or if they are constant with missing data everywhere in the data. Therefore, it is still a good practice to identify these columns and verify that they do not contain any useful information before removing them from the dataset.

Viewing a sizable sample of 40 datapoints where the constant string value of 'Crops and livestock products' has been replaced with

To show columns with all exact same entries, you can use the nunique() method to count the number of unique values in each column. If the result is 1, it means all entries in the column are the same. Here's an example code snippet that shows how to do this for a pandas DataFrame called df: This code first creates a list comprehension that iterates over all columns in df and checks if the number of unique values in each column is equal to 1. The resulting list same$_{e}ntry_{c}olscontainsthenamesofallcolumnswhereallentriesarethesame.$

You can modify this code to fit your specific DataFrame and column name

2.4 Casting the Value floats to integer

s

It is better to have data stored in the most appropriate data types for readability, memory and computational reasons. Integer data types use less memory than float data types, so storing integer data in integer form can save memory and speed up processing times. But incorrectly modelling discreet values as real numbers has profound implications for mathematical outcomes in feature engineering. There is a distinction between discrete mathematics, which deals with countable quantities such as integers, and continuous mathematics, which deals with uncountable quantities such as real numbers (Van Der Walt, Colbert, and Varoquaux 2011).

When working with discrete data, it is often important to use integer data types to ensure that mathematical operations are well-defined and that rounding errors and other issues do not arise. On the other hand, continuous data is typically represented using floating-point data types, which can represent a wider range of values but are subject to rounding and precision errors that can affect the results of mathematical operations.

In the case of cattle count data, it is clearly a countable quantity so long as the animals are alive as they are for this dataset and will be represented using the integer data type. Therefore we **cast the data from a float to an integer** to make the most efficient use of memory and to avoid potential inaccuracies when working with the data.

2.5 Categorical flagging for official, estimated, unofficial and missing figures

Categorical flagging for official, estimated, unofficial and missing figures can impact statistical analysis and needed be considered here. The flag descriptions for reported stock figures are official, estimated, unofficial or are missing and all are represented in the FAOSTAT dataset (Contu et al. 2019). Two questions arose:

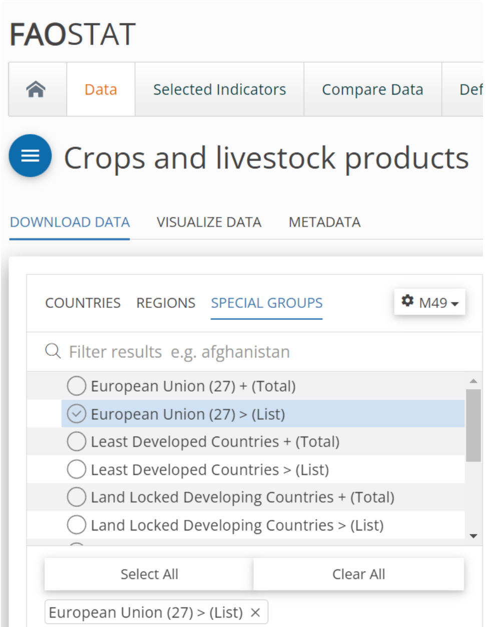
- Will estimation and unofficially sourced data contaminate the study or broaden confidence intervals?
- What is the geographical and temporal distribution of missing figures?

A list of countries with any missing entries reads Austria, Belgium, Belgium-Luxembourg, Bulgaria, Croatia, Cyprus, Czechia, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden

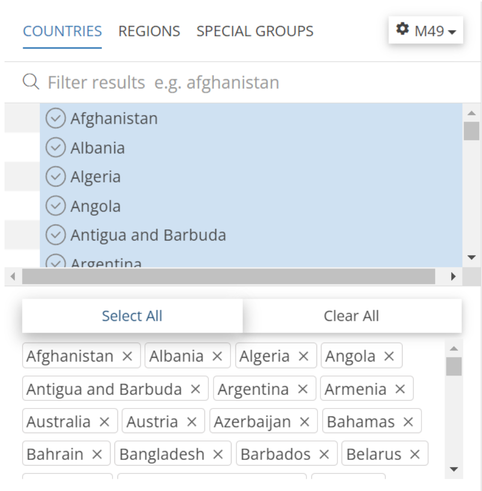
Belgium-Luxembourg is not a country and it was discovered to be some sort of text processing concatenation error and was dropped from the dataset.

2.6 Data quality processing

After loading the live cattle stock data into a pandas dataframe, we observed missing values. This data reflects the number of cattle in stock or alive in a country during a particular year. For example, the dataset shows that there were 6,649,310 cattle in stock in Ireland in 2021. As the number of cattle in stock is an important variable for our study, it is crucial to carefully consider the missing values. If a



(a) Filtering to the European Union (EU) 27 on FAOSTAT leads to spurious country data and if this is varient will cause problems



(b) downloading supersets for the 195 recognised independent states in the world and data cleaning techniques will be adopted for the rest of the data retrieval

Figure 2.1: The decision to download a larger dataset than necessary was made to ensure a high level of certainty in the workflow, given the relatively small size of the datasets involved. By having a larger dataset, it may be easier to identify and correct any errors or inconsistencies that may arise during the data analysis process.

significant number of missing values correspond to Ireland and are recent, it could impact our research question. To gain a better understanding of the missing values, we quantified and analyzed them. Table 2.6 shows that 319 values are missing, which accounts for 18.7% of the data. This percentage is too high to delete records without a valid reason. Figure provides a visual representation of the missing data.

2.7 data completeness analysis by country

There are only 10 countries with missing data as seen in table so these could be filtered out in that time interval but as suggested farming in the 20th centuary was significantly different than now so data from any country back then is low in relevance for modelling and prediction.

Drop Belgium-Luxembourg

2.8 data completeness analysis by year

In order to better understand the dataset, we performed a data completeness analysis by year. The data covers the number of cattle in stock in the European Union (EU) member countries from 1961 to 2021. To assess how the missing values are distributed over time, we created a new table that tallied the number of missing values in each row of the dataset, grouped by year. We then visualised this distribution using a bar chart, which can be found in Figure 2.3. The last significant improvements in completeness step was from 1999 to 2000 and for this and the fact that beef farming technology has changed so much since the 20th centuary the decision is made to

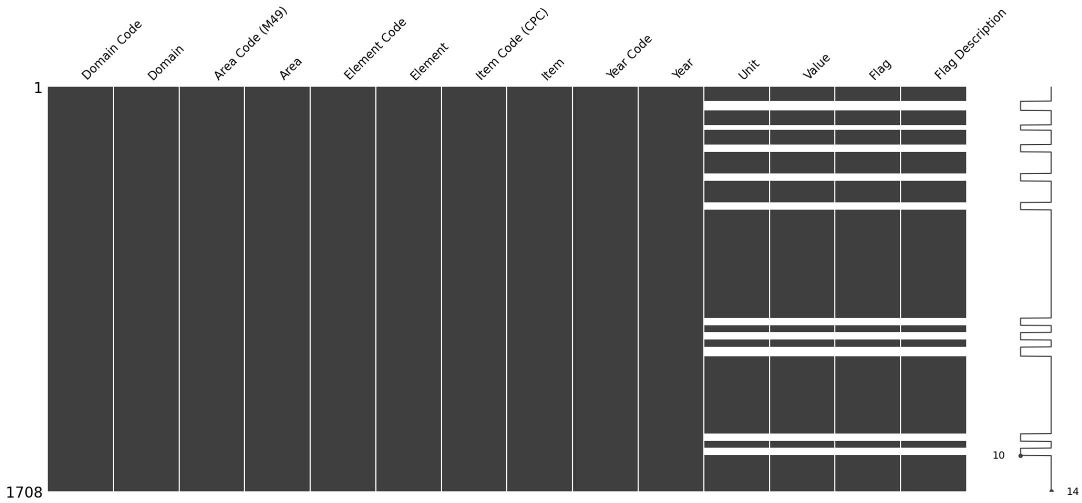


Figure 2.2: The figure shows 10 unnamed countries represented by horizontal strip having a significant proportion of missing data. The missingno package provides a matrix() function to create a missing value matrix plot. This plot visualizes the missingness in the data by showing where values are missing with white bars.

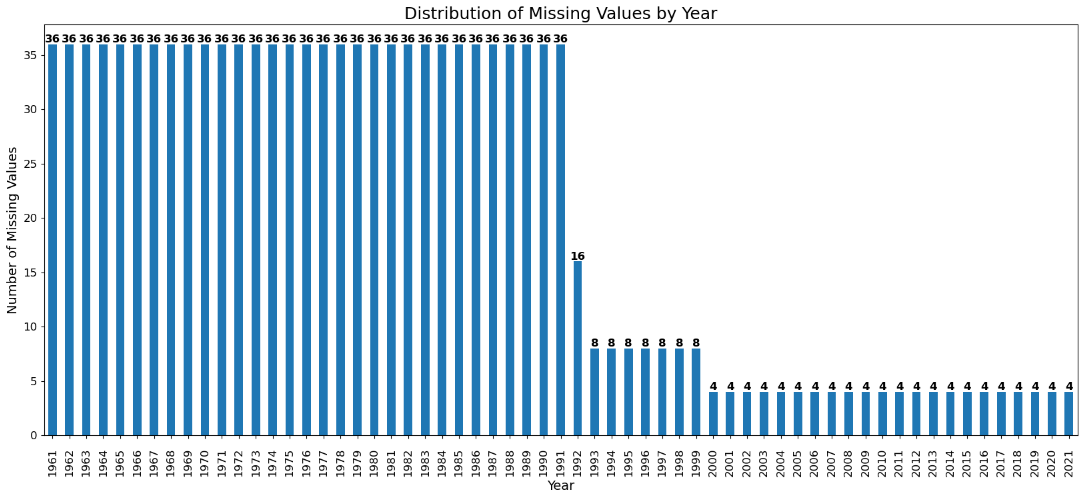

Figure 2.3: Distribution of missing values by year. The initial data studied gives the number of cattle in stock in the European Union (EU) member countries. The data spans from 1961 to 2021 and so it is natural to ascertain how the errors distribute across that interval. We created a new table that counted the number of missing values in each row of the dataset, grouped by year. Then we made a bar chart that showed the distribution of missing values by year

Table 2.7: Livestock stocks in various countries, with a focus on cattle. Each row corresponds to a particular country, with information on the year, unit, and number of cattle stocks. Some rows also include information on the reliability or official status of the data (indicated by the "Flag" column).

Appendix A

Deflator

In economics, a deflator is a measure used to adjust nominal values for inflation, allowing for comparison with real, inflation-adjusted values. The deflator is calculated by dividing a nominal value (such as GDP or a price index) by a price index representing the general level of prices in the economy.

In Exploratory Data Analysis (EDA), deflators can be used to adjust for inflation when analyzing historical data. For example, if you are analyzing sales data over several years, it may be necessary to adjust for inflation to get a true sense of how sales have changed over time. By using a deflator, you can convert nominal values (such as sales revenue) into real values (inflation-adjusted sales revenue), which makes it easier to compare values across different time periods.

Deflators can also be useful when analyzing economic data, such as GDP or employment figures. By using a deflator to adjust for inflation, you can get a more accurate picture of how the economy is performing over time. For example, if GDP has increased by 10

In summary, deflators are an important tool in both economics and data analysis, as they allow us to adjust for inflation and make accurate comparisons of values over time.

Appendix B

Data analysis

Data analysis is the process of inspecting, cleaning, transforming, and modeling data with the goal of discovering useful information, drawing conclusions, and supporting decision-making. It involves various methods and techniques such as descriptive statistics, inferential statistics, data visualization, and machine learning.

Data analysis can be applied in a variety of fields, including business, finance, healthcare, social sciences, and engineering, among others. In business, for example, data analysis can be used to analyze customer behavior, identify trends, and make predictions about future sales. In healthcare, data analysis can be used to identify risk factors for diseases, develop treatment plans, and monitor the effectiveness of interventions.

The process of data analysis typically involves several steps, including defining the problem or research question, collecting and preparing the data, exploring and visualizing the data, performing statistical analyses, interpreting the results, and communicating the findings. Effective data analysis requires a combination of technical skills, critical thinking, and domain knowledge.
